

Equation-Free function toolbox for Matlab/Octave: Full Developers Manual

A. J. Roberts* John Maclean† J. E. Bunder‡ et al.§

February 16, 2019

Abstract

This ‘equation-free toolbox’ empowers the computer-assisted analysis of complex, multiscale systems. Its aim is to enable you to use microscopic simulators to perform system level tasks and analysis. The methodology bypasses the derivation of macroscopic evolution equations by using only short bursts of microscale simulations which are often the best available description of a system (Kevrekidis & Samaey 2009, Kevrekidis et al. 2004, 2003, e.g.). This suite of functions should empower users to start implementing such methods—but so far we have only just started.

2.7 To do/discuss	37
-----------------------------	----

This section provides some good projective integration functions (Gear & Kevrekidis 2003a,b, Givon et al. 2006, ?, e.g.). The goal is to enable computationally expensive dynamic simulations to be run over long time scales.

Scenario When you are interested in a complex system with many interacting parts or agents, you usually are primarily interested in the self-organised emergent macroscale characteristics. Projective integration empowers us to efficiently simulate such long-time emergent dynamics. We suppose you have coded some accurate, fine scale simulation of the complex system, and call such code a *microsolver*.

The Projective Integration section of this toolbox consists of several functions. Each function implements over the long-time scale a variant of a standard numerical method to simulate the emergent dynamics of the complex system. Each function has standardised inputs and outputs.

Main functions

- Projective Integration by second or fourth order Runge–Kutta, `PIRK2()` and `PIRK4()` respectively. These schemes are suitable for precise simulation of the slow dynamics, provided the time period spanned by an application of the *microsolver* is not too large.
- Projective Integration with a General solver, `PIG()`. This function enables a Projective Integration implementation of any solver with macroscale time steps. It does not matter whether the solver is a standard Matlab or Octave algorithm, or one supplied by the user. As explored in later examples, `PIG()` should only be used in very stiff systems.
- ‘Constraint-defined manifold computing’, `cdmc()`. This helper function, based on the method introduced in ?, iteratively applies the *microsolver* and projects the output backwards in time. The result is to constrain the fast variables close to the slow manifold, without advancing the

current time by the duration of an application of the microsolver. This function can be used to reduce errors related to the simulation length of the microsolver in either the **PIRK** or **PIG** functions. In particular, it enables **PIG()** to be used on problems that are not particularly stiff.

The above functions share dependence on a user-specified ‘microsolver’, that accurately simulates some problem of interest.

The following sections describe the **PIRK2()** and **PIG()** functions in detail, providing an example for each. Then **PIRK4()** is very similar to **PIRK2()**. Descriptions for the minor functions follow, and an example of the use of **cdmc()**.

2.1 **PIRK2(): projective integration of second order accuracy**

This Projective Integration scheme implements a macroscale scheme that is analogous to the second-order Runge–Kutta Improved Euler integration.

```
18 function [x, tms, xms, rm, svf] = PIRK2(microBurst, bT, tSpan, x0)
```

Input If there are no input arguments, then this function applies itself to the Michaelis–Menton example: see the code in [Section 2.1.1](#) as a basic template of how to use.

- **microBurst()**, a user-coded function that computes a short-time burst of the microscale simulation.

```
[tOut, xOut] = microBurst(tStart, xStart, bT)
```

- Inputs: **tStart**, the start time of a burst of simulation; **xStart**, the row n -vector of the starting state; **bT**, the total time to simulate in the burst.
- Outputs: **tOut**, the column vector of solution times; and **xOut**, an array in which each *row* contains the system state at corresponding times.

- **bT**, a scalar, the minimum amount of time needed for simulation of the microBurst to relax the fast variables to the slow manifold.
- **tSpan** is an ℓ -vector of times at which the user requests output, of which the first element is always the initial time. **PIRK2()** does not use adaptive time stepping; the macroscale time steps are (nearly) the steps between elements of **tSpan**.
- **x0** is an n -vector of initial values at the initial time **tSpan(1)**. Elements of **x0** may be **NaN**: they are included in the simulation and output, and often represent boundaries in space fields.

Choose a long enough burst length Suppose: you have some desired relative accuracy ε that you wish to achieve (e.g., $\varepsilon \approx 0.01$ for two digit accuracy); the slow dynamics of your system occurs at rate/frequency of magnitude about α ; and the rate of *decay* of your fast modes are faster than the lower bound β (e.g., if the fast modes decay roughly like $e^{-12t}, e^{-34t}, e^{-56t}$ then $\beta \approx 12$). Then choose

1. a macroscale time step, $\Delta = \text{diff}(\mathbf{tSpan})$, such that $\alpha\Delta \approx \sqrt{6\varepsilon}$, and
2. a microscale burst length, $\delta = \mathbf{bT} \gtrsim \frac{1}{\beta} \log(\beta\Delta)$ (see [Figure 1](#)).

Output If there are no output arguments specified, then a plot is drawn of the computed solution **x** versus **tSpan**.

- **x**, an $\ell \times n$ array of the approximate solution vector. Each row is an estimated state at the corresponding time in **tSpan**. The simplest usage is then **x** = **PIRK2(microBurst,bT,tSpan,x0)**.

However, microscale details of the underlying Projective Integration computations may be helpful. **PIRK2()** provides two to four optional outputs of the microscale bursts.

- **tms**, optional, is an L dimensional column vector containing microscale times of burst simulations, each burst separated by **NaN**;

Figure 1: Need macroscale step Δ such that $|\alpha\Delta| \lesssim \sqrt{6\varepsilon}$ for given relative error ε and slow rate α , and then $\delta/\Delta \gtrsim \frac{1}{\beta\Delta} \log \beta\Delta$ determines the minimum required burst length δ for given fast rate β .

- **xms**, optional, is an $L \times n$ array of the corresponding microscale states—this data is an accurate simulation of the state and may help visualise more details of the solution.
- **rm**, optional, a struct containing the ‘remaining’ applications of the microBurst required by the Projective Integration method during the calculation of the macrostep:
 - **rm.t** is a column vector of microscale times; and
 - **rm.x** is the array of corresponding burst states.

The states **rm.x** do not have the same physical interpretation as those in **xms**; the **rm.x** are required in order to estimate the slow vector field during the calculation of the Runge–Kutta increments, and do not in general resemble the true dynamics.

- **svf**, optional, a struct containing the Projective Integration estimates

of the slow vector field.

- `svf.t` is a 2ℓ dimensional column vector containing all times at which the Projective Integration scheme is extrapolated along microBurst data to form a macrostep.
- `svf.dx` is a $2\ell \times n$ array containing the estimated slow vector field.

2.1.1 If no arguments, then execute an example

```
158 if nargin==0
```

Example code for Michaelis–Menton dynamics The Michaelis–Menten enzyme kinetics is expressed as a singularly perturbed system of differential equations for $x(t)$ and $y(t)$ (encoded in function `MMburst` in the next paragraph):

$$\frac{dx}{dt} = -x + (x + \frac{1}{2})y \quad \text{and} \quad \frac{dy}{dt} = \frac{1}{\epsilon} [x - (x + 1)y].$$

With initial conditions $x(0) = 1$ and $y(0) = 0$, the following code computes and plots a solution over time $0 \leq t \leq 6$ for parameter $\epsilon = 0.05$. Since the rate of decay is $\beta \approx 1/\epsilon$ we choose a burst length $\epsilon \log(\Delta/\epsilon)$ as here the macroscale time step $\Delta = 1$.

```
178 epsilon = 0.05
179 ts = 0:6
180 bT = epsilon*log((ts(2)-ts(1))/epsilon)
181 [x,tms,xms] = PIRK2(@MMburst, bT, ts, [1;0]);
182 figure, plot(ts,x,'o:',tms,xms)
183 title('Projective integration of Michaelis--Menten enzyme kinetics')
184 xlabel('time t'), legend('x(t)','y(t)')
```

Upon finishing execution of the example, exit this function.

```
190 return
191 end%if no arguments
```

Example function code for a burst of ODEs Integrate a burst of length `bT` of the ODEs for the Michaelis–Menten enzyme kinetics at parameter ϵ inherited from above. Code ODEs in function `dMMdt` with variables $x = \mathbf{x}(1)$ and $y = \mathbf{x}(2)$. Starting at time `ti`, and state `xi` (row), we here simply use `ode23` to integrate in time.

```

205 function [ts, xs] = MMburst(ti, xi, bT)
206     dMMdt = @(t,x) [ -x(1)+(x(1)+0.5)*x(2)
207                     1/epsilon*( x(1)-(x(1)+1)*x(2) ) ];
208     [ts, xs] = ode23(dMMdt, [ti ti+bT], xi);
209 end

```

2.1.2 The projective integration code

Determine the number of time steps and preallocate storage for macroscale estimates.

```

235 nT=length(tSpan);
236 x=nan(nT,length(x0));

```

Get the number of expected outputs and set logical indices to flag what data should be saved.

```

244 nArgs=nargout();
245 saveMicro = (nArgs>1);
246 saveFullMicro = (nArgs>3);
247 saveSvf = (nArgs>4);

```

Run a preliminary application of the `microBurst` on the initial conditions to help relax to the slow manifold. This is done in addition to the `microBurst` in the main loop, because the initial conditions are often far from the attracting slow manifold. Require the user to input and output rows of the system state.

```

260 x0 = reshape(x0,1,[]);
261 [relax_t,relax_x0] = microBurst(tSpan(1),x0,bT);

```

Use the end point of the `microBurst` as the initial conditions.

```

269 tSpan(1) = tSpan(1)+bT;
270 x(1,:)=relax_x0(end,:);

```

If saving information, then record the first application of the microBurst. Allocate cell arrays for times and states for outputs requested by the user, as concatenating cells is much faster than iteratively extending arrays.

```

280 if saveMicro
281     tms = cell(nT,1);
282     xms = cell(nT,1);
283     tms{1} = reshape(relax_t,[],1);
284     xms{1} = relax_x0;
285     if saveFullMicro
286         rm.t = cell(nT,1);
287         rm.x = cell(nT,1);
288         if saveSvf
289             svf.t = nan(2*nT-2,1);
290             svf.dx = nan(2*nT-2,length(x0));
291         end
292     end
293 end

```

Loop over the macroscale time steps

```

301 for jT = 2:nT
302     T = tSpan(jT-1);

```

If two applications of the microBurst would cover the entire macroscale time-step, then do so (setting some internal states to **NaN**); else proceed to projective step.

```

310     if 2*abs(bT)>=abs(tSpan(jT)-T) & bT*(tSpan(jT)-T)>0
311         [t1,xm1] = microBurst(T, x(jT-1,:), tSpan(jT)-T);
312         x(jT,:) = xm1(end,:);
313         t2=nan; xm2=nan(1,size(xm1,2));
314         dx1=xm2; dx2=xm2;
315     else

```

Run the first application of the microBurst; since this application directly follows from the initial conditions, or from the latest macrostep, this microscale information is physically meaningful as a simulation of the system. Extract the size of the final time step.

```

326     [t1,xm1] = microBurst(T, x(jT-1,:), bT);
327     del = t1(end)-t1(end-1);

```

Check for round-off error.

```

333     xt=[reshape(t1(end-1:end),[],1) xm1(end-1:end,:)];
334     roundingTol=1e-8;
335     if norm(diff(xt))/norm(xt,'fro') < roundingTol
336         warning(['significant round-off error in 1st projection at T=' num2str(T) 'nu
337     end

```

Find the needed time step to reach time `tSpan(n+1)` and form a first estimate `dx1` of the slow vector field.

```

346     Dt = tSpan(jT)-T-bT;
347     dx1 = (xm1(end,:)-xm1(end-1,:))/del;

```

Project along `dx1` to form an intermediate approximation of `x`; run another application of the microBurst and form a second estimate of the slow vector field.

```

357     xint = xm1(end,:) + (Dt-bT)*dx1;
358     [t2,xm2] = microBurst(T+Dt, xint, bT);
359     del = t2(end)-t2(end-1);
360     dx2 = (xm2(end,:)-xm2(end-1,:))/del;

```

Check for round-off error.

```

366     xt=[reshape(t2(end-1:end),[],1) xm2(end-1:end,:)];
367     if norm(diff(xt))/norm(xt,'fro') < roundingTol
368         warning(['significant round-off error in 2nd projection at T=' num2str(T) 'nu
369     end

```

Use the weighted average of the estimates of the slow vector field to take a macrostep.

```
377     x(jT,:) = xm1(end,:) + Dt*(dx1+dx2)/2;
```

Now end the if-statement that tests whether a projective step saves simulation time.

```
385     end
```

If saving trusted microscale data, then populate the cell arrays for the current loop iterate with the time steps and output of the first application of the microBurst. Separate bursts by NaNs.

```
395     if saveMicro
396         tms{jT} = [reshape(t1,[],1); nan];
397         xms{jT} = [xm1; nan(1,size(xm1,2))];
```

If saving all microscale data, then repeat for the remaining applications of the microBurst.

```
405     if saveFullMicro
406         rm.t{jT} = [reshape(t2,[],1); nan];
407         rm.x{jT} = [xm2; nan(1,size(xm2,2))];
```

If saving Projective Integration estimates of the slow vector field, then populate the corresponding cells with times and estimates.

```
416         if saveSvf
417             svf.t(2*jT-3:2*jT-2) = [t1(end); t2(end)];
418             svf.dx(2*jT-3:2*jT-2,:) = [dx1; dx2];
419         end
420     end
421 end
```

Terminate the main loop:

```
427 end
```

Overwrite `x(1,:)` with the specified initial condition `tSpan(1)`.

```
436 x(1,:) = reshape(x0,1,[]);
```

For additional requested output, concatenate all the cells of time and state data into two arrays.

```

444 if saveMicro
445     tms = cell2mat(tms);
446     xms = cell2mat(xms);
447     if saveFullMicro
448         rm.t = cell2mat(rm.t);
449         rm.x = cell2mat(rm.x);
450     end
451 end

```

2.1.3 If no output specified, then plot simulation

```

459 if nArgs==0
460     figure, plot(tSpan,x,'o:')
461     title('Projective Simulation with PIRK2')
462 end

```

This concludes **PIRK2()**.

```

469 end

```

2.2 **PIG(): Projective Integration via a General macroscale integrator**

This is an approximate Projective Integration scheme when the macroscale integrator is any coded scheme. The advantage is that one may use MATLAB/Octave's inbuilt integration functions, with all their sophisticated error control and adaptive time-stepping, to do the macroscale simulation.

Unlike the **PIRKn** functions, **PIG()** does not estimate the slow vector field at the times expected by any user-specified scheme, but instead provides an estimate of the slow vector field at a slightly different time, after an application of the micro-burst simulator. Consequently **PIG()** will incur an

additional global error term proportional to the burst length of the microscale simulator. For that reason, **PIG()** should be used with

- either very stiff problems, in which the burst length of the micro-burst can be short,
- or the ‘constraint defined manifold’ based micro-burst provided by **cdmc()**, that attempts to project the variables onto the slow manifold without affecting the time.

36 `function [t,x,tms,xms,svf] = PIG(macroInt,microBurst,tSpan,x0)`

The inputs and outputs are a little different to the two **PIRKn** functions.

Inputs:

- **microBurst()** is a function that produces output from the user-specified code for a burst of micro-scale simulation. The function must know how long a burst it is to use. Usage

`[tbs,xbs] = microBurst(tb0,xb0)`

Inputs: **tb0** is the start time of a burst; **xb0** is the vector state at the start of a burst.

Outputs: **tbs**, the vector of solution times; and **xbs**, the corresponding states.

- **macroInt()**, the numerical method that the user wants to apply on a slow-time macroscale. Either use a standard MATLAB/Octave integration function (such as **ode23** or **ode45**), or code this solver as a standard MATLAB/Octave integration function. That is, if you code you own, then it must be

`[ts,xs] = macroInt(f,tSpan,x0)`

where function **f(t,x)** notionally evaluates the time derivatives $d\vec{x}/dt$ at ‘any’ time; **tSpan** is either the macro-time interval, or the vector of times at which a macroscale value is to be returned; and **x0** are the

initial values of \vec{x} at time `tSpan(1)`. Then the i th row of `xs`, `xs(i,:)`, is to be the vector $\vec{x}(t)$ at time $t = \text{ts}(i)$. Remember that in `PIG()` the function $\mathbf{f}(\mathbf{t}, \mathbf{x})$ is to be estimated by Projective Integration burst.

- `tSpan`, a vector of times at which the user requests output, of which the first element is always the initial time. If `macroInt` can adaptively select time steps (e.g., `ode45`), then `tSpan` can consist of an initial and final time only.
- `x0`, the vector of initial values at the initial time `tSpan(1)`.

Output If there are no output arguments specified, then a plot is drawn of the computed solution `x` versus `t`. Most often you would only store the first two output results of `PIG()`, via say `[t,x] = PIG(...)`.

- `t`, an ℓ -vector of times at which `macroInt` produced results.
- `x`, an $\ell \times n$ array of the computed solution: the i th row of `x`, `x(i,:)`, is to be the vector $\vec{x}(t)$ at time $t = \text{t}(i)$.

However, microscale details of the underlying Projective Integration computations may be helpful, and so `PIG()` some optional outputs of the microscale bursts.

- `tms`, optional, is an L dimensional column vector containing microscale times of burst simulations, each burst separated by `NaN`;
- `xms`, optional, is an $L \times n$ array of the corresponding microscale states—this data is an accurate simulation of the state and may help visualise more details of the solution.
- `svf`, optional, a struct containing the Projective Integration estimates of the slow vector field.
 - `svf.t` is a 2ℓ dimensional column vector containing all times at which the Projective Integration scheme is extrapolated along microsolver data to form a macrostep.
 - `svf.dx` is a $2\ell \times n$ array containing the estimated slow vector field.

2.2.1 If no arguments, then execute an example

```
132 if nargin==0
```

As a basic example, consider a singularly perturbed system of differential equations for $\vec{x}(t) = (x_1(t), x_2(t))$:

$$\frac{dx_1}{dt} = \cos(x_1) \sin(x_2) \cos(t) \quad \text{and} \quad \frac{dx_2}{dt} = \frac{1}{\epsilon} [\cos(x_1) - x_2].$$

With initial conditions $\vec{x}(0) = (1, 0)$, the following code computes and plots a solution of the system over time $0 \leq t \leq 6$ for parameter $\epsilon = 10^{-3}$.

First we code the right-hand side function of the microscale system of ODEs.

```
149 epsilon = 1e-3;
150 dxdt=@(t,x) [ cos(x(1))*sin(x(2))*cos(t)
151               (cos(x(1))-x(2))/epsilon ];
```

Second, we code microscale bursts, here using the standard `ode45()`. Since the rate of decay is $\beta \approx 1/\epsilon$ we choose a burst length $2\epsilon \log(1/\epsilon)$ as here we do not know the macroscale time step invoked by `marcoInt()`, so blithely use $\Delta = 1$, and then double the usual formula for safety.

```
163 bT = 2*epsilon*log(1/epsilon)
164 microBurst = @(tb0,xb0) ode45(dxdt,[tb0 tb0+bT],xb0);
```

Third, invoke **PIG** to use `ode23()`, say, on the macroscale slow evolution. Integrate the micro-bursts over $0 \leq t \leq 6$ from initial condition $\vec{x} = (1, 0)$. (You could set `tSpan=[0 -6]` to integrate backwards in time with forward bursts.)

```
174 tSpan = [0 6];
175 [ts,xs,tms,xms] = PIG('ode23',microBurst,tSpan,[1 0]);
```

Plot output of this projective integration.

```
181 figure, plot(ts,xs,'o:',tms,xms)
182 title('Projective integration of singular perturbed ODE')
183 xlabel('time t'), legend('x_1(t)', 'x_2(t)')
```

Upon finishing execution of the example, exit this function.

```
189 return
190 end%if no arguments
```

Find the number of time steps at which output is expected, and the number of variables.

```
205 nT=length(tSpan)-1;
206 nx = length(x0);
```

Get the number of expected outputs and set logical indices to flag what data should be saved.

```
214 nArgs=nargout();
215 saveMicro = (nArgs>1);
216 saveSvf = (nArgs>2);
```

Run a first application of the microBurst on the initial conditions. This is done in addition to the microBurst in the main loop, because the initial conditions are often far from the attracting slow manifold.

```
228 x0 = reshape(x0,[],1);
229 [relax_t,relax_x0] = microBurst(tSpan(1),x0);
```

Update the initial time.

```
236 tSpan(1) = relax_t(end); %tSpan(1)+bT;
```

Allocate cell arrays for times and states for any of the outputs requested by the user. If saving information, then record the first application of the microBurst. Note that it is unknown a priori how many applications of the microBurst will be required; this code may be run more efficiently if the correct number is used in place of **nT+1** as the dimension of the cell arrays.

```
248 if saveMicro
249     tms=cell(nT+1,1); xms=cell(nT+1,1);
250     n=1;
251     tms{n} = reshape(relax_t,[],1);
252     xms{n} = relax_x0;
```

```

253
254     if saveSvf
255         svf.t = cell(nT+1,1);
256         svf.dx = cell(nT+1,1);
257     end
258 end

```

The idea of **PIG()** is to use the output from the microBurst to approximate an unknown function **ff(t,x)**, that describes the slow dynamics. This approximation is then used in the system/user-defined ‘coarse solver’ **macroInt()**. The approximation is described in

```

270 function [dx]=genProjection(tt,xx)

```

Run a microBurst from the given initial conditions.

```

276     [t_tmp,x_micro_tmp] = microBurst(tt,reshape(xx,[],1));

```

Compute the standard Projective Integration approximation of the slow vector field.

```

283         del = t_tmp(end)-t_tmp(end-1);
284         dx = (x_micro_tmp(end,:)-x_micro_tmp(end-1,:))'/(del);

```

Save the microscale data, and the Projective Integration slow vector field, if requested.

```

291         if saveMicro
292             n=n+1;
293             tms{n} = [reshape(t_tmp,[],1); nan];
294             xms{n} = [x_micro_tmp; nan(1,nx)];
295             if saveSvf
296                 svf.t{n-1} = tt;
297                 svf.dx{n-1} = dx;
298             end
299             end
300 end% function genProjection()

```

Define the approximate slow vector field according to Projective Integration.

```
309 ff=@(t,x) genProjection(t,x);
```

Do Projective Integration of `ff()` with the user-specified `microBurst`.

```
318 [t,x]=feval(macroInt,ff,tSpan,relax_x0(end,:));
```

Overwrite `x(1,:)` and `t(1)`, which the user expect to be `x0` and `tSpan(1)` respectively, with the given initial conditions.

```
327 x(1,:) = x0';
```

```
328 t(1) = tSpan(1);
```

For each additional requested output, concatenate all the cells of time and state data into two arrays. Then, return the two arrays in a cell.

```
344 if saveMicro
```

```
345     tms = cell2mat(tms);
```

```
346     xms = cell2mat(xms);
```

```
347     if saveSvf
```

```
348         svf.t = cell2mat(svf.t);
```

```
349         svf.dx = cell2mat(svf.dx);
```

```
350     end
```

```
351 end
```

2.2.2 If no output specified, then plot simulation

```
359 if nArgs==0
```

```
360     figure, plot(t,x,'o:')
```

```
361     title('Projective Simulation via PIG')
```

```
362 end
```

This concludes `PIG()`.

```
370 end
```

2.3 PIRK4(): projective integration of fourth order accuracy

This Projective Integration scheme implements a macrosolver analogous to the fourth order Runge–Kutta method.

```
16 function [x, tms, xms, rm, svf] = PIRK4(solver, bT, tSpan, x0)
```

See [Section 2.1](#) as the inputs and outputs are the same as `PIRK2()`.

If no arguments, then execute an example

```
27 if nargin==0
```

Example of Michaelis–Menton backwards in time The Michaelis–Menten enzyme kinetics is expressed as a singularly perturbed system of differential equations for $x(t)$ and $y(t)$ (encoded in function `MMburst`):

$$\frac{dx}{dt} = -x + (x + \frac{1}{2})y \quad \text{and} \quad \frac{dy}{dt} = \frac{1}{\epsilon} [x - (x + 1)y].$$

With initial conditions $x(0) = y(0) = 0.2$, the following code uses forward time bursts in order to integrate backwards in time to $t = -5$. It plots the computed solution over time $-5 \leq t \leq 0$ for parameter $\epsilon = 0.1$. Since the rate of decay is $\beta \approx 1/\epsilon$ we choose a burst length $\epsilon \log(|\Delta|/\epsilon)$ as here the macroscale time step $\Delta = -1$.

```
48 epsilon = 0.1
49 ts = 0:-1:-5
50 bT = epsilon*log(abs(ts(2)-ts(1))/epsilon)
51 [x,tms,xms,rm,svf] = PIRK4(@MMburst, bT, ts, 0.2*[1;1]);
52 figure, plot(ts,x,'o:',tms,xms)
53 xlabel('time t'), legend('x(t)','y(t)')
54 title('Backwards-time projective integration of Michaelis--Menten')
```

Upon finishing execution of the example, exit this function.

```
60 return
61 end%if no arguments
```

Example function code for a burst of ODEs Integrate a burst of length `bT` of the ODEs for the Michaelis–Menten enzyme kinetics at parameter ϵ inherited from above. Code ODEs in function `dMMdt` with variables $x = \mathbf{x}(1)$ and $y = \mathbf{x}(2)$. Starting at time `ti`, and state `xi` (row), we here simply use `ode23` to integrate in time.

```

75 function [ts, xs] = MMburst(ti, xi, bT)
76     dMMdt = @(t,x) [ -x(1)+(x(1)+0.5)*x(2)
77                     1/epsilon*( x(1)-(x(1)+1)*x(2) ) ];
78     [ts, xs] = ode23(dMMdt, [ti ti+bT], xi);
79 end

```

Input

- `solver()`, a function that produces output from the user-specified code for microscale simulation.

`[tOut, xOut] = solver(tStart, xStart, tSim)`

- Inputs: `tStart`, the start time of a burst of simulation; `xStart`, the row n -vector of the starting state; `tSim`, the total time to simulate in the burst.
- Outputs: `tOut`, the column vector of solution times; and `xOut`, an array in which each *row* contains the system state at corresponding times.
- `bT`, a scalar, the minimum amount of time needed for simulation of the microsolver to relax the fast variables to the slow manifold.
- `tSpan` is an ℓ -vector of times at which the user requests output, of which the first element is always the initial time. `PIRK4()` does not use adaptive time stepping; the macroscale time steps are (nearly) the steps between elements of `tSpan`.
- `x0` is an n -vector of initial values at the initial time `tSpan(1)`. Elements of `x0` may be `NaN`: they are included in the simulation and output, and often represent boundaries in space fields.

Output If there are no output arguments specified, then a plot is drawn of the computed solution **x** versus **tSpan**.

- **x**, an $\ell \times n$ array of the approximate solution vector. Each row is an estimated state at the corresponding time in **tSpan**. The simplest usage is then **x** = **PIRK4(solver,bT,tSpan,x0)**.

However, microscale details of the underlying Projective Integration computations may be helpful. **PIRK4()** provides two to four optional outputs of the microscale bursts.

- **tms**, optional, is an L dimensional column vector containing microscale times of burst simulations, each burst separated by **NaN**;
- **xms**, optional, is an $L \times n$ array of the corresponding microscale states—this data is an accurate simulation of the state and may help visualise more details of the solution.
- **rm**, optional, a struct containing the ‘remaining’ applications of the microsolver required by the Projective Integration method during the calculation of the macrostep:
 - **rm.t** is a column vector of microscale times; and
 - **rm.x** is the array of corresponding burst states.

The states **rm.x** do not have the same physical interpretation as those in **xms**; the **rm.x** are required in order to estimate the slow vector field during the calculation of the Runge–Kutta increments, and do not in general resemble the true dynamics.

- **svf**, optional, a struct containing the Projective Integration estimates of the slow vector field.
 - **svf.t** is a 4ℓ dimensional column vector containing all times at which the Projective Integration scheme is extrapolated along microsolver data to form a macrostep.
 - **svf.dx** is a $4\ell \times n$ array containing the estimated slow vector field.

2.3.1 The projective integration code

Determine the number of time steps and preallocate storage for macroscale estimates.

```

176 nT=length(tSpan);
177 x=nan(nT,length(x0));

```

Get the number of expected outputs and set logical indices to flag what data should be saved.

```

185 nArgs=nargout();
186 saveMicro = (nArgs>1);
187 saveFullMicro = (nArgs>3);
188 saveSvf = (nArgs>4);

```

Run a preliminary application of the microsolver on the initial conditions to help relax to the slow manifold. This is done in addition to the microsolver in the main loop, because the initial conditions are often far from the attracting slow manifold. Require the user to input and output rows of the system state.

```

201 x0 = reshape(x0,1,[]);
202 [relax_t,relax_x0] = solver(tSpan(1),x0,bT);

```

Use the end point of the microsolver as the initial conditions.

```

210 tSpan(1) = tSpan(1)+bT;
211 x(1,:)=relax_x0(end,:);

```

If saving information, then record the first application of the microsolver. Allocate cell arrays for times and states for outputs requested by the user, as concatenating cells is much faster than iteratively extending arrays.

```

221 if saveMicro
222     tms = cell(nT,1);
223     xms = cell(nT,1);
224     tms{1} = reshape(relax_t,[],1);
225     xms{1} = relax_x0;
226     if saveFullMicro

```

```

227         rm.t = cell(nT,1);
228         rm.x = cell(nT,1);
229         if saveSvf
230             svf.t = nan(4*nT-4,1);
231             svf.dx = nan(4*nT-4,length(x0));
232         end
233     end
234 end

```

Loop over the macroscale time steps

```

242 for jT = 2:nT
243     T = tSpan(jT-1);

```

If four applications of the microsolver would cover the entire macroscale time-step, then do so (setting some internal states to **NaN**); else proceed to projective step.

```

252     if 4*abs(bT)>=abs(tSpan(jT)-T) & bT*(tSpan(jT)-T)>0
253         [t1,xm1] = solver(T, x(jT-1,:), tSpan(jT)-T);
254         x(jT,:) = xm1(end,:);
255         t2=nan; xm2=nan(1,size(xm1,2));
256         t3=nan; t4=nan; xm3=xm2; xm4 = xm2; dx1=xm2; dx2=xm2;
257     else

```

Run the first application of the microsolver; since this application directly follows from the initial conditions, or from the latest macrostep, this microscale information is physically meaningful as a simulation of the system. Extract the size of the final time step.

```

268         [t1,xm1] = solver(T, x(jT-1,:), bT);
269         del = t1(end)-t1(end-1);

```

Check for round-off error.

```

275         xt=[reshape(t1(end-1:end),[],1) xm1(end-1:end,:)];
276         roundingTol=1e-8;
277         if norm(diff(xt))/norm(xt,'fro') < roundingTol

```

```

278     warning(['significant round-off error in 1st projection at T=' num2str(T) 'nu
279     end

```

Find the needed time step to reach time `tSpan(n+1)` and form a first estimate `dx1` of the slow vector field.

```

288     Dt = tSpan(jT)-T-bT;
289     dx1 = (xm1(end,:)-xm1(end-1,:))/del;

```

Project along `dx1` to form an intermediate approximation of `x`; run another application of the microsolver and form a second estimate of the slow vector field.

```

299     xint = xm1(end,:) + (Dt/2-bT)*dx1;
300     [t2,xm2] = solver(T+Dt/2, xint, bT);
301     del = t2(end)-t2(end-1);
302     dx2 = (xm2(end,:)-xm2(end-1,:))/del;
303
304     xint = xm1(end,:) + (Dt/2-bT)*dx2;
305     [t3,xm3] = solver(T+Dt/2, xint, bT);
306     del = t3(end)-t3(end-1);
307     dx3 = (xm3(end,:)-xm3(end-1,:))/del;
308
309     xint = xm1(end,:) + (Dt-bT)*dx3;
310     [t4,xm4] = solver(T+Dt, xint, bT);
311     del = t4(end)-t4(end-1);
312     dx4 = (xm4(end,:)-xm4(end-1,:))/del;

```

Check for round-off error.

```

318     xt=[reshape(t2(end-1:end),[],1) xm2(end-1:end,:)];
319     if norm(diff(xt))/norm(xt,'fro') < roundingTol
320     warning(['significant round-off error in 2nd projection at T=' num2str(T) 'nu
321     end

```

Use the weighted average of the estimates of the slow vector field to take a macrostep.

```

329     x(jT,:) = xm1(end,:) + Dt*(dx1 + 2*dx2 + 2*dx3 + dx4)/6;

```

Now end the if-statement that tests whether a projective step saves simulation time.

```
337     end
```

If saving trusted microscale data, then populate the cell arrays for the current loop iterate with the time steps and output of the first application of the microsolver. Separate bursts by NaNs.

```
347     if saveMicro
348         tms{jT} = [reshape(t1,[],1); nan];
349         xms{jT} = [xm1; nan(1,size(xm1,2))];
```

If saving all microscale data, then repeat for the remaining applications of the microsolver.

```
357         if saveFullMicro
358             rm.t{jT} = [reshape(t2,[],1); nan;...
359                         reshape(t3,[],1); nan;...
360                         reshape(t4,[],1); nan];
361             rm.x{jT} = [xm2; nan(1,size(xm2,2));...
362                         xm3; nan(1,size(xm2,2));...
363                         xm4; nan(1,size(xm2,2))];
```

If saving Projective Integration estimates of the slow vector field, then populate the corresponding cells with times and estimates.

```
372         if saveSvf
373             svf.t(4*jT-7:4*jT-4) = [t1(end); t2(end); t3(end); t4
374             svf.dx(4*jT-7:4*jT-4,:) = [dx1; dx2; dx3; dx4];
375         end
376     end
377 end
```

Terminate the main loop:

```
383 end
```

Overwrite `x(1,:)` with the specified initial condition `tSpan(1)`.

```
392 x(1,:) = reshape(x0,1,[]);
```

For additional requested output, concatenate all the cells of time and state data into two arrays.

```
400 if saveMicro
401     tms = cell2mat(tms);
402     xms = cell2mat(xms);
403     if saveFullMicro
404         rm.t = cell2mat(rm.t);
405         rm.x = cell2mat(rm.x);
406     end
407 end
```

2.3.2 If no output specified, then plot simulation

```
415 if nArgs==0
416     figure, plot(tSpan,x,'o:')
417     title('Projective Simulation with PIRK4')
418 end
```

This concludes `PIRK4()`.

```
425 end
```

2.3.3 `cdmc()`

`cdmc()` iteratively applies the micro-burst and then projects backwards in time to the initial conditions. The cumulative effect is to relax the variables to the attracting slow manifold, while keeping the final time for the output the same as the input time.

```
13 function [ts, xs] = cdmc(microBurst,t0,x0)
```

Input

- `microBurst()`, a black box micro-burst function suitable for Projective Integration. See any of `PIRK2()`, `PIRK4()`, or `PIG()` for a description of `microBurst()`.
- `t0`, an initial time
- `x0`, an initial state

Output

- `ts`, a vector of times. `tout(end)` will equal `t`.
- `xs`, an array of state estimates produced by `microBurst()`.

This function is a wrapper for the micro-burst. For instance if the problem of interest is a dynamical system that is not too stiff, and which can be simulated by the microBurst `sol(t,x,T)`, one would define

```
cSol = @(t,x) cdmc(sol,t,x) |
```

and thereafter use `csol()` in place of `sol()` as the microBurst for any Projective Integration scheme. The original microBurst `sol()` could create large errors if used in a Projective Integration scheme, but the output of `cdmc()` should not.

Begin with a standard application of the micro-burst.

```
41 [ts,xs] = feval(microBurst,t0,x0);
42 bT = ts(end)-ts(1);
```

Project backwards to before the initial time, then simulate just one burst forward to obtain a simulation burst that ends at the original `t0`.

```
50 dxdt = (xs(end,:) - xs(end-1,:))/(ts(end,:) - ts(end-1,:));
51 x0 = xs(end,:)-2*bT*dxdt;
52 t0 = ts(1)-bT;
53 [ts,xs] = feval(microBurst,t0,x0.');
```

2.4 Example: PI using Runge–Kutta macrosolvers

This script is a demonstration of the `PIRK()` schemes, that use a Runge–Kutta macrosolver, applied to a simple linear system with some slow and fast directions.

Clear workspace and set a seed.

```
14 clear
15 rng(1)
```

The majority of this example involves setting up details for the microsolver. We use a simple function `gen_linear_system()` that outputs a function $f(t, x) = \mathbf{A}\vec{x} + \vec{b}$, where \mathbf{A} has some eigenvalues with large negative real part, corresponding to fast variables and some eigenvalues with real part close to zero, corresponding to slow variables. The function `gen_linear_system()` requires that we specify bounds on the real part of the strongly stable eigenvalues,

```
30 fastband = [-5e2; -1e2];
```

and bounds on the real part of the weakly stable/unstable eigenvalues,

```
37 slowband = [-0.002; 0.002];
```

We now generate a random linear system with seven fast and three slow variables.

```
44 f = gen_linear_system(7,3,fastband,slowband);
```

Set the time step size and total integration time of the microsolver.

```
51 dt = 0.001;
52 bT = 0.05;
```

As a rule of thumb, the time steps `dt` should satisfy $dt \leq 1/|\text{fastband}(1)|$ and the time to simulate with each application of the microsolver, `micro.bT`, should be larger than or equal to $1/|\text{fastband}(2)|$. We set the integration scheme to be used in the microsolver. Since the time steps are so small, we just use the forward Euler scheme

```
64 solver='fe';
```

(Other options: `'rk2'` for second order Runge–Kutta, `'rk4'` for fourth order, or any Matlab/Octave integrator such as `'ode45'`.)

A crucial part of the PI philosophy is that it does not assume anything about the microsolver. For this reason, the microsolver must be a ‘black box’, which is run by specifying an initial time and state, and a duration to simulate for. All the details of the microsolver must be set by the user. We generate and save a black box microsolver.

```
81 bbm = bbgen(solver,f,dt);
82 solver = bbm;
```

Set the macroscale times at which we request output from the PI scheme and the initial conditions.

```
90 tSpan=0: 1 : 30;
91 IC = linspace(-10,10,10);
```

We implement the PI scheme, saving the coarse states in `x`, the ‘trusted’ applications of the microsolver in `xmicro`, and the additional applications of the microsolver in `xrmicro`. Note that the second and third outputs are optional and do not need to be set.

```
105 [x, tms, xms, rm] = PIRK4(solver, bT, tSpan, IC);
```

For verification, we also compute the trajectories using a standard solver.

```
112 [tt,ode45x] = ode45(f,tSpan([1,end]),IC);
```

Figure 2 plots the output.

```
128 tmsr = rm.t; xmsr = rm.x;
129 clf()
130 hold on
131 PI_sol=plot(tSpan,x,'bo');
132 std_sol=plot(tt,ode45x,'r');
133 plot(tms,xms,'k. ');
134 plot(tmsr,xmsr,'g.');
```

Figure 2: Demonstration of `PIRK4()`. From initial conditions, the system rapidly transitions to an attracting invariant manifold. The PI solution accurately tracks the evolution of the variables over time while requiring only a fraction of the computations of the standard solver.

```

135 legend([PI_sol(1),std_sol(1)],'PI Solution',...
136         'Standard Solution','Location','NorthWest')
137 xlabel('Time');
138 ylabel('State');

```

Save plot to a file.

```

144 set(gcf,'PaperPosition',[0 0 14 10])
145 print('-depsc2','PIRK')

```

2.5 Example: Projective Integration using General macrosolvers

In this example the Projective Integration-General scheme is applied to a singularly perturbed ordinary differential equation. The aim is to use a standard non-stiff numerical integrator, such as `ode45()`, on the slow, long-time macroscale. For this stiff system, `PIG()` is an order of magnitude faster than ordinary use of `ode45`.

```
16 clear all, close all
```

Set time scale separation and model.

```
23 epsilon = 1e-4;
24 dxdt=@(t,x) [ cos(x(1))*sin(x(2))*cos(t)
25               (cos(x(1))-x(2))/epsilon ];
```

Set the ‘black box’ macrosolver to be an integration using a standard solver, and set the standard time of simulation for the macrosolver.

```
34 bT = epsilon*log(1/epsilon);
35 microBurst = @(tb0, xb0) ode45(dxdt,[tb0 tb0+bT],xb0);
```

Set initial conditions, and the time to be covered by the macrosolver.

```
43 x0 = [1 1.4];
44 tSpan=[0 15];
```

Now time and integrate the above system over `tspan` using `PIG()` and, for comparison, a brute force implementation of `ode45()`. Report the time taken by each method.

```
53 tic
54 [ts,xs,tms,xms] = PIG('ode45',microBurst,tSpan,x0);
55 tPIGusingODE45asMacro = toc
56 tic
57 [t45,x45] = ode45(dxdt,tSpan,x0);
58 tODE45alone = toc
```

Figure 3: Accurate simulation of a stiff nonautonomous system by `PIG()`. The microsolver is called on-the-fly by the macrosolver `ode45`.

Plot the output on two figures, showing the truth and macrosteps on both, and all applications of the microsolver on the first figure.

```

68 figure
69 h = plot(ts,xs,'o', t45,x45,'-', tms,xms,'.');
70 legend(h(1:2:5),'PI Solution','ode45 Solution','PI microsolver')
71 xlabel('Time'), ylabel('State')
72
73 figure
74 h = plot(ts,xs,'o', t45,x45,'-');
75 legend(h([1 3]),'PI Solution','ode45 Solution')
76 xlabel('Time'), ylabel('State')
77 set(gcf,'PaperPosition',[0 0 14 10]), print('-depsc2','PIGExample')

```

Figure 3 plots the output.

- The problem may be made more, or less, stiff by changing the time-

scale separation parameter $\epsilon = \text{epsilon}$. The compute time of `PIG()` is almost independent of ϵ , whereas that of `ode45()` is proportional to $1/\epsilon$.

But if the problem is insufficiently stiff (larger ϵ), then `PIG()` produces nonsense. This nonsense is overcome by `cdmc()` (Section 2.6).

- The mildly stiff problem in Section 2.4 may be efficiently solved by a standard solver (e.g., `ode45()`). The stiff but low dimensional problem in this example can be solved efficiently by a standard stiff solver (e.g., `ode15s()`). The real advantage of the Projective Integration schemes is in high dimensional stiff problems, that cannot be efficiently solved by most standard methods.

2.6 Explore: Projective Integration using constraint-defined manifold computing

In this example the Projective Integration-General scheme is applied to a singularly perturbed ordinary differential equation in which the time scale separation is not large. The resulting simulation is not accurate. In parallel, we run the same scheme but with `cdmc()` used as a wrapper for the microsolver. This second implementation successfully replicates the true dynamics.

```
16 clear all, close all
```

Set a weak time scale separation and model.

```
23 epsilon = 0.01;
24 dxdt=@(t,x) [ cos(x(1))*sin(x(2))*cos(t)
25               (cos(x(1))-x(2))/epsilon ];
```

Set the ‘naive’ microsolver to be an integration using a standard solver, and set the standard time of simulation for the microsolver.

```
34 bT = epsilon*log(1/epsilon);
35 naiveBurst = @(tb0,xb0) ode45(dxdt,[tb0 tb0+bT],xb0);
```

Create a second struct in which the solver is the output of `cdmc()`.

Figure 4: Accurate simulation of a weakly stiff non-autonomous system by `PIG()` using `cdmc()`, and an inaccurate solution using a naive application of `PIG()`.

```
42 cBurst = @(t,x) cdmc(naiveBurst,t,x);
```

Set initial conditions, and the time to be covered by the macrosolver.

```
50 x0 = [1 0];
51 tSpan=0:0.5:15;
```

Simulate using `PIG()` with each of the above macrosolvers. Generate a trusted solution using standard numerical methods.

```
61 [nt,nx] = PIG('ode45',naiveBurst,tSpan,x0);
62 [ct,cx] = PIG('ode45',cBurst,tSpan,x0);
63 [t45,x45] = ode45(dxdt,tSpan([1 end]),x0);
```

Figure 4 plots the output.

```

79 figure
80 h = plot(nt,nx,'o', ct,cx,'+', t45,x45,'-');
81 legend(h(1:2:5),'Naive PIG','PIG + cdmc','Accurate')
82 xlabel('Time'), ylabel('State')
83 set(gcf,'PaperPosition',[0 0 14 10]), print('-depsc2','PIGExplore')

```

The source of the error in the standard `PIG()` scheme is the burst length `bT`, that is significant on the slow time scale. Set `bT` to `20*epsilon` or `50*epsilon`¹ to worsen the error in both schemes. This example reflects a general principle, that most Projective Integration schemes will incur a global error term which is proportional to the simulation time of the microsolver and independent of the order of the microsolver. The `PIRK()` schemes have been written to minimise, if not eliminate entirely, this error, but by design `PIG()` works with any user-defined macrosolver and cannot reduce this error. The function `cdmc()` reduces this error term by attempting to mimic the microsolver without advancing time.

2.7 To do/discuss

- could implement Projective Integration by ‘arbitrary’ Runge–Kutta scheme; that is, by having the user input a particular Butcher table—surely only specialists would be interested
- can ‘reverse’ the order of projection and microsolver applications with a little fiddling. Then output at each user-requested coarse time is the end point of an application of the microsolver - better predictions for fast variables.
- Can maybe implement microsolvers that terminate a burst when the fast dynamics have settled using, for example, the ‘Events’ function handle in `ode23`.

¹this example is quite extreme: at `bT=50*epsilon`, it would be computationally much cheaper to simulate the entire length of `tSpan` using the microsolver alone.

The patch scheme applies to spatio-temporal systems where the spatial domain is larger than what can be computed in reasonable time. Then one may simulate only on small patches of the space-time domain, and produce correct macroscale predictions by craftily coupling the patches across unsimulated space (Hyman 2005, Samaey et al. 2005, 2006, Roberts & Kevrekidis 2007, Liu et al. 2015, e.g.).

The spatial structure is to be on a lattice such as obtained from finite difference approximation of a PDE. Usually continuous in time.

Quick start For an example, see Sections 3.1.1 and 3.4.1 for basic code that uses the provided functions to simulate Burgers’ PDE and a nonlinear ‘diffusion’ PDE.

3.1 configPatches1(): configures spatial patches in 1D

Subsubsection contents

	Input	39
	Output	40
3.1.1	If no arguments, then execute an example	41
	Example of Burgers PDE inside patches	42
3.1.2	The code to make patches	43

Makes the struct `patches` for use by the patch/gap-tooth time derivative function `patchSmooth1()`. Section 3.1.1 lists an example of its use.

14 function configPatches1(fun,Xlim,BCs,nPatch,ordCC,ratio,nSubP,nEdge)

15 global patches

Input If invoked with no input arguments, then executes an example of simulating Burgers’ PDE—see Section 3.1.1 for the example code.

- `fun` is the name of the user function, `fun(t,u,x)`, that computes time derivatives (or time-steps) of quantities on the patches.

- **Xlim** give the macro-space domain of the computation: patches are equi-spaced over the interior of the interval $[\text{Xlim}(1), \text{Xlim}(2)]$.
- **BCs** somehow will define the macroscale boundary conditions. Currently, **BCs** is ignored and the system is assumed macro-periodic in the domain.
- **nPatch** is the number of equi-spaced spaced patches.
- **ordCC** is the ‘order’ of interpolation across empty space of the macroscale mid-patch values to the edge of the patches for inter-patch coupling: currently must be *geq* -1 .
- **ratio** (real) is the ratio of the half-width of a patch to the spacing of the patch mid-points: so **ratio** $= \frac{1}{2}$ means the patches abut; and **ratio** $= 1$ is overlapping patches as in holistic discretisation.
- **nSubP** is the number of equi-spaced microscale lattice points in each patch. Must be odd so that there is a central lattice point.
- **nEdge** is, for each patch, the number of edge values set by interpolation at the edge regions of each patch. May be omitted. The default is one (suitable for microscale lattices with only nearest neighbour interactions).

Output The *global* struct **patches** is created and set with the following components.

- **.fun** is the name of the user’s function **fun(u,t,x)** that computes the time derivatives (or steps) on the patchy lattice.
- **.ordCC** is the specified order of inter-patch coupling.
- **.alt** is true for interpolation using only odd neighbouring patches as for staggered grids, and false for the usual case of all neighbour coupling.
- **.Cwtsr** and **.Cwtsl** are the **ordCC**-vector of weights for the inter-patch interpolation onto the right and left edges (respectively) with patch:macroscale ratio as specified.

- `.x` is `nSubP × nPatch` array of the regular spatial locations x_{ij} of the microscale grid points in every patch.
- `.nEdge` is, for each patch, the number of edge values set by interpolation at the edge regions of each patch.

3.1.1 If no arguments, then execute an example

```
79 if nargin==0
```

The code here shows one way to get started: a user's script may have the following three steps (arrows indicate function recursion).

1. `configPatches1`
2. `ode15s` integrator \leftrightarrow `patchSmooth1` \leftrightarrow user's `burgersPDE`
3. process results

Establish global patch data struct to interface with a function coding Burgers' PDE: to be solved on 2π -periodic domain, with eight patches, spectral interpolation couples the patches, each patch of half-size ratio 0.2, and with seven points within each patch.

```
97 configPatches1(@BurgersPDE,[0 2*pi], nan, 8, 0, 0.2, 7);
```

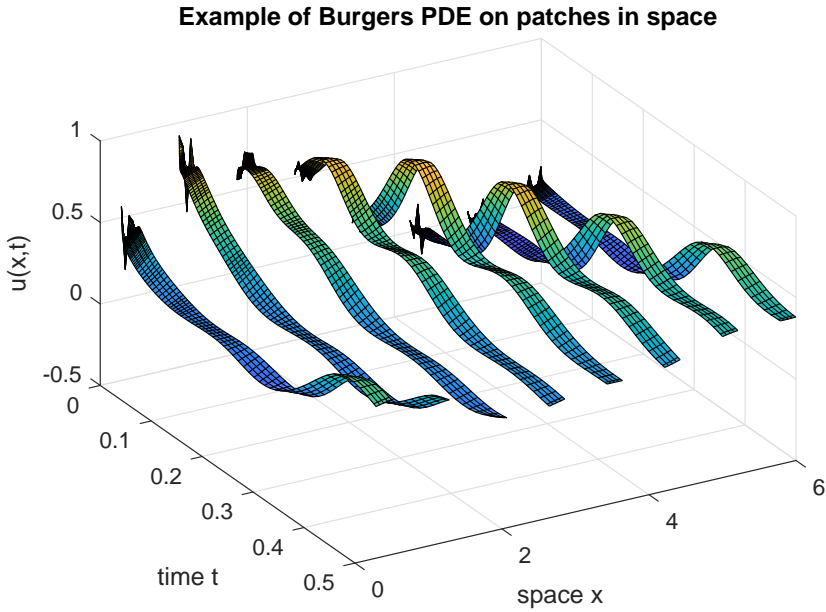

Set an initial condition, and integrate in time using standard functions.

```
104 u0=0.3*(1+sin(patches.x))+0.1*randn(size(patches.x));
105 [ts,ucts]=ode15s(@patchSmooth1,[0 0.5],u0(:));
```

Plot the simulation using only the microscale values interior to the patches: set x -edges to `nan` to leave the gaps. [Figure 5](#) illustrates an example simulation in time generated by the patch scheme applied to Burgers' PDE.

```
115 figure(1),clf
116 patches.x([1 end],:)=nan;
117 surf(ts,patches.x(:),ucts'), view(60,40)
118 title('Example of Burgers PDE on patches in space')
119 xlabel('time t'), ylabel('space x'), zlabel('u(x,t)')
```

Figure 5: field $u(x, t)$ of the patch scheme applied to Burgers' PDE.

Upon finishing execution of the example, exit this function.

```

130 return
131 end%if no arguments

```

Example of Burgers PDE inside patches As a microscale discretisation of $u_t = u_{xx} - 30uu_x$, code $\dot{u}_{ij} = \frac{1}{\delta x^2}(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) - 30u_{ij}\frac{1}{2\delta x}(u_{i+1,j} - u_{i-1,j})$.

```

141 function ut=BurgersPDE(t,u,x)
142     dx=diff(x(1:2)); % micro-scale spacing
143     i=2:size(u,1)-1; % interior points in patches
144     ut=nan(size(u)); % preallocate storage
145     ut(i,:)=diff(u,2)/dx^2 ...
146         -30*u(i,:).*(u(i+1,:)-u(i-1,:))/(2*dx);
147 end

```

3.1.2 The code to make patches

Set one edge-value to compute by interpolation if not specified by the user.
Store in the struct.

```

155 if nargin<8, nEdge=1; end
156 if nEdge>1, error('multi-edge-value interp not yet implemented'), end
157 if 2*nEdge+1>nSubP, error('too many edge values requested'), end
158 patches.nEdge=nEdge;

```

First, store the pointer to the time derivative function in the struct.

```

165 patches.fun=fun;

```

Second, store the order of interpolation that is to provide the values for the inter-patch coupling conditions. Spectral coupling is **ordCC** of 0 and -1 .

```

173 if (ordCC<-1) | ~(floor(ordCC)==ordCC)
174     error('ordCC out of allowed range integer>-2')
175 end

```

For odd **ordCC** do interpolation based upon odd neighbouring patches as is useful for staggered grids.

```

182 patches.alt=mod(ordCC,2);
183 ordCC=ordCC+patches.alt;
184 patches.ordCC=ordCC;

```

Check for staggered grid and periodic case.

```

190 if patches.alt & (mod(nPatch,2)==1)
191     error('Require an even number of patches for staggered grid')
192 end

```

Might as well precompute the weightings for the interpolation of field values for coupling. (Could sometime extend to coupling via derivative values.)

```

200 patches.Cwtsr=zeros(ordCC,1);
201 if patches.alt % eqn (7) in \cite{Cao2014a}
202     patches.Cwtsr(1:2:ordCC)=[1 ...

```

```

203     cumprod((ratio^2-(1:2:(ordCC-2)).^2)/4)./ ...
204     factorial(2*(1:(ordCC/2-1))))];
205 patches.Cwtsr(2:2:ordCC)=[ratio/2 ...
206     cumprod((ratio^2-(1:2:(ordCC-2)).^2)/4)./ ...
207     factorial(2*(1:(ordCC/2-1))+1)*ratio/2];
208 else %
209     patches.Cwtsr(1:2:ordCC)=(cumprod(ratio^2- ...
210         (((1:(ordCC/2))-1)).^2)./factorial(2*(1:(ordCC/2))-1)/ratio);
211     patches.Cwtsr(2:2:ordCC)=(cumprod(ratio^2- ...
212         (((1:(ordCC/2))-1)).^2)./factorial(2*(1:(ordCC/2)))));
213 end
214 patches.Cwtsl=(-1).^((1:ordCC)'+patches.alt).*patches.Cwtsr;

```

Third, set the centre of the patches in a the macroscale grid of patches assuming periodic macroscale domain.

```

221 X=linspace(Xlim(1),Xlim(2),nPatch+1);
222 X=X(1:nPatch)+diff(X)/2;
223 DX=X(2)-X(1);

```

Construct the microscale in each patch, assuming Dirichlet patch edges, and a half-patch length of **ratio · DX**.

```

231 if mod(nSubP,2)==0, error('configPatches1: nSubP must be odd'), end
232 i0=(nSubP+1)/2;
233 dx=ratio*DX/(i0-1);
234 patches.x=bsxfun(@plus,dx*(-i0+1:i0-1)',X); % micro-grid
235 end% function

```

Fin.

3.2 patchSmooth1(): interface to time integrators

Subsubsection contents

Input	45
Output	45

To simulate in time with spatial patches we often need to interface a users time derivative function with time integration routines such as `ode15s` or `PIRK2`. This function provides an interface. It assumes that the sub-patch structure is *smooth* so that the patch centre-values are sensible macroscale variables, and patch edge values are determined by macroscale interpolation of the patch-centre values. Communicate patch-design variables to this function using the previously established global struct `patches`.

```
23 function dudt=patchSmooth1(t,u)
24 global patches
```

Input

- `u` is a vector of length `nSubP · nPatch · nVars` where there are `nVars` field values at each of the points in the `nSubP × nPatch` grid.
- `t` is the current time to be passed to the user's time derivative function.
- `patches` a struct set by `configPatches1()` with the following information used here.
 - `.fun` is the name of the user's function `fun(t,u,x)` that computes the time derivatives on the patchy lattice. The array `u` has size `nSubP × nPatch × nVars`. Time derivatives must be computed into the same sized array, but herein the patch edge values are overwritten by zeros.
 - `.x` is `nSubP × nPatch` array of the spatial locations x_{ij} of the microscale grid points in every patch. Currently it *must* be an equi-spaced lattice on both macro- and micro-scales.

Output

- `dudt` is `nSubP · nPatch · nVars` vector of time derivatives, but with patch edge values set to zero.

Reshape the fields `u` as a 2/3D-array, and sets the edge values from macroscale interpolation of centre-patch values. [Section 3.3](#) describes `patchEdgeInt1()`.

```
68 u=patchEdgeInt1(u);

Ask the user function for the time derivatives computed in the array, overwrite
its edge values with the dummy value of zero, then return to a to the user/
integrator as column vector.

78 dudt=patches.fun(t,u,patches.x);
79 dudt([1 end],:,:)=0;
80 dudt=reshape(dudt,[],1);

Fin.
```

3.3 patchEdgeInt1(): sets edge values from interpolation over the macroscale

Subsubsection contents

Input	46
Output	47
Lagrange interpolation gives patch-edge values	48
Case of spectral interpolation	49

Couples 1D patches across 1D space by computing their edge values from macroscale interpolation patch core averging. This function is primarily used by `patchSmooth1` but is also useful for user graphics. Consequently a spatially discrete system could be integrated in time via the patch or gap-tooth scheme (Roberts & Kevrekidis 2007). Assumes that the core averaged structure is *smooth* so that these averages are sensible macroscale variables, and patch edge values are determined by macroscale interpolation of the core averaged values (?). Communicate patch-design variables via the global struct `patches`.

```
23 function u=patchEdgeInt1(u)
24 global patches
```

Input

3.3 `patchEdgeInt1()`: sets edge values from interpolation over the macroscale⁴⁷

- `u` is a vector of length `nSubP · nPatch · nVars` where there are `nVars` field values at each of the points in the `nSubP × nPatch` grid.
- `patches` a struct set by `configPatches1()` which includes the following.
 - `.x` is `nSubP × nPatch` array of the spatial locations x_{ij} of the microscale grid points in every patch. Currently it *must* be an equi-spaced lattice on both macro- and micro-scales.
 - `.ordCC` is order of interpolation integer ≥ -1 .
 - `.alt` in $\{0, 1\}$ is one for staggered grid (alternating) interpolation.
 - `.Cwtsr` and `.Cwtsl` define the coupling.

Output

- `u` is `nSubP × nPatch × nVars` 2/3D array of the fields with edge values set by interpolation of patch core averages.

Determine the sizes of things. Any error arising in the reshape indicates `u` has the wrong size.

```
57 [nSubP,nPatch]=size(patches.x);
58 nVars=round(numel(u)/numel(patches.x));
59 if numel(u)~=nSubP*nPatch*nVars
60     nSubP=nSubP, nPatch=nPatch, nVars=nVars, sizeu=size(u)
61     end
62 u=reshape(u,nSubP,nPatch,nVars);
```

Compute lattice sizes from inside the patches as the edge values may be NaNs, etc.

```
69 dx=patches.x(3,1)-patches.x(2,1);
70 DX=patches.x(2,2)-patches.x(2,1);
```

If the user has not defined the patch core, then we assume it to be a single point in the middle of the patch. For `patches.nCore` $\neq 1$ the half width ratio is reduced, as described by ?.

```

79 if ~isfield(patches,'nCore')
80     patches.nCore=1;
81 end
82 r=dx*(nSubP-1)/2/DX*(nSubP - patches.nCore)/(nSubP - 1);

```

For the moment assume the physical domain is macroscale periodic so that the coupling formulas are simplest. Should eventually cater for periodic, odd-mid-gap, even-mid-gap, even-mid-patch, Dirichlet, Neumann etc. These index vectors point to patches and their two immediate neighbours.

```

93 j=1:nPatch; jp=mod(j,nPatch)+1; jm=mod(j-2,nPatch)+1;

```

Calculate centre of each patch and the surrounding core. (**nSubP** and **nCore** are both odd)

```

100 i0=round((nSubP+1)/2);
101 c=round((patches.nCore-1)/2);

```

Lagrange interpolation gives patch-edge values so compute centred differences of the patch core averages for the macro-interpolation of all fields. Assumes the domain is macro-periodic.

```

111 if patches.ordCC>0 % then non-spectral interpolation
112     if patches.EnsAve
113         ucore=sum(mean(u((i0-c):(i0+c),j,:),3),1)';
114         dmu=zeros(patches.ordCC,nPatch);
115     else
116         ucore=reshape(sum(u((i0-c):(i0+c),j,:),1),nPatch,nVars);
117         dmu=zeros(patches.ordCC,nPatch,nVars);
118     end;
119     if patches.alt % use only odd numbered neighbours
120         dmu(1,:,:)=(ucore(jp,:)+ucore(jm,:))/2; % \mu
121         dmu(2,:,:)=(ucore(jp,:)-ucore(jm,:)); % \delta
122         jp=jp(jp); jm=jm(jm); % increase shifts to \pm 2
123     else % standard
124         dmu(1,j,:)=(ucore(jp,:)-ucore(jm,:))/2; % \mu\delta

```

3.3 `patchEdgeInt1()`: sets edge values from interpolation over the macroscale 49

```

125     dmu(2,j,:)=(ucore(jp,:)-2*ucore(j,:)+ucore(jm,:))/2; % \delta^2
126 end% if odd/even

```

Recursively take δ^2 of these to form higher order centred differences (could unroll a little to cater for two in parallel).

```

134 for k=3:patches.ordCC
135     dmu(k,,:)=dmu(k-2,jp,:)-2*dmu(k-2,j,:)+dmu(k-2,jm,:);
136 end

```

Interpolate macro-values to be Dirichlet edge values for each patch ([Roberts & Kevrekidis 2007](#), ?), using weights computed in `configPatches1()`. Here interpolate to specified order.

```

144 if patches.EnsAve
145     u(nSubP,j,:)= repmat(ucore(j) *(1-patches.alt) ...
146         +sum(bsxfun(@times,patches.Cwtsr,dmu)), [1,1,nVars]) ...
147     -sum(u((nSubP-patches.nCore+1):(nSubP-1),:,:),1);
148     u(1,j,:)= repmat(ucore(j) *(1-patches.alt) ...
149         +sum(bsxfun(@times,patches.Cwtsl,dmu)), [1,1,nVars]) ...
150     -sum(u(2:patches.nCore,:,:),1);
151 else
152     u(nSubP,j,:)=ucore(j,:)*(1-patches.alt) ...
153     + reshape(-sum(u((nSubP-patches.nCore+1):(nSubP-1),j,:),1) ...
154         +sum(bsxfun(@times,patches.Cwtsr,dmu)), nPatch,nVars);
155     u(1,j,:)=ucore(j,:)*(1-patches.alt) ...
156     +reshape(-sum(u(2:patches.nCore,j,:),1) ...
157         +sum(bsxfun(@times,patches.Cwtsl,dmu)), nPatch,nVars);
158 end;

```

Case of spectral interpolation Assumes the domain is macro-periodic. As the macroscale fields are N -periodic, the macroscale Fourier transform writes the centre-patch values as $U_j = \sum_k C_k e^{ik2\pi j/N}$. Then the edge-patch values $U_{j\pm r} = \sum_k C_k e^{ik2\pi/N(j\pm r)} = \sum_k C'_k e^{ik2\pi j/N}$ where $C'_k = C_k e^{ikr2\pi/N}$. For `nPatch` patches we resolve ‘wavenumbers’ $|k| < \text{nPatch}/2$, so set row vector `ks` = $k2\pi/N$ for ‘wavenumbers’ $k = (0, 1, \dots, k_{\max}, -k_{\max}, \dots, -1)$ for

odd N , and $k = (0, 1, \dots, k_{\max}, \pm(k_{\max} + 1), -k_{\max}, \dots, -1)$ for even N .

```
174 else% spectral interpolation
```

Deal with staggered grid by doubling the number of fields and halving the number of patches (`configPatches1` tests there are an even number of patches). Then the patch-ratio is effectively halved. The patch edges are near the middle of the gaps and swapped.

```
184 if patches.alt % transform by doubling the number of fields
185     v=nan(size(u)); % currently to restore the shape of u
186     u=cat(3,u(:,1:2:nPatch,:),u(:,2:2:nPatch,:));
187     altShift=reshape(0.5*[ones(nVars,1);-ones(nVars,1)],1,1,[]);
188     iV=[nVars+1:2*nVars 1:nVars]; % scatter interp to alternate field
189     r=r/2; % ratio effectively halved
190     nPatch=nPatch/2; % halve the number of patches
191     nVars=nVars*2; % double the number of fields
192 else % the values for standard spectral
193     altShift=0;
194     iV=1:nVars;
195 end
```

Now set wavenumbers.

```
201 kMax=floor((nPatch-1)/2);
202 ks=2*pi/nPatch*(mod((0:nPatch-1)+kMax,nPatch)-kMax);
```

Test for reality of the field values, and define a function accordingly.

```
209 if imag(u(i0,:,:))==0, uclean=@(u) real(u);
210 else uclean=@(u) u;
211 end
```

Compute the Fourier transform of the patch centre-values for all the fields. If there are an even number of points, then zero the zig-zag mode in the FT and add it in later as cosine.

```
220 Ck=fft(u(i0,:,:));
221 if mod(nPatch,2)==0
```

```

222     Czz=Ck(1,nPatch/2+1,:)/nPatch;
223     Ck(1,nPatch/2+1,:)=0;
224 end

```

The inverse Fourier transform gives the edge values via a shift a fraction r to the next macroscale grid point. Enforce reality when appropriate.

```

232     u(nSubP,:,iV)=uclean(ifft(bsxfun(@times,Ck ...
233         ,exp(1i*bsxfun(@times,ks,altShift+r)))));
234     u( 1,:,iV)=uclean(ifft(bsxfun(@times,Ck ...
235         ,exp(1i*bsxfun(@times,ks,altShift-r)))));

```

For an even number of patches, add in the cosine mode.

```

241     if mod(nPatch,2)==0
242         cosr=cos(pi*(altShift+r+(0:nPatch-1)));
243         u(nSubP,:,iV)=u(nSubP,:,iV)+uclean(bsxfun(@times,Czz,cosr));
244         cosr=cos(pi*(altShift-r+(0:nPatch-1)));
245         u( 1,:,iV)=u( 1,:,iV)+uclean(bsxfun(@times,Czz,cosr));
246     end

```

Restore staggered grid when appropriate. Is there a better way to do this??

```

253 if patches.alt
254     nVars=nVars/2; nPatch=2*nPatch;
255     v(:,1:2:nPatch,:)=u(:, :, 1:nVars);
256     v(:,2:2:nPatch,:)=u(:, :, nVars+1:2*nVars);
257     u=v;
258 end
259 end% if spectral

```

Fin, returning the 2/3D array of field values.

3.4 *configPatches2(): configures spatial patches in 2D*

Subsubsection contents

	Output	53
3.4.1	If no arguments, then execute an example	54
	Example of nonlinear diffusion PDE inside patches . .	56
3.4.2	The code to make patches	57

Makes the struct `patches` for use by the patch/gap-tooth time derivative function `patchSmooth2()`. Section 3.4.1 lists an example of its use.

```

17 function configPatches2(fun,Xlim,BCs,nPatch,ordCC,ratio,nSubP,nEdge)
18 global patches

```

Input If invoked with no input arguments, then executes an example of simulating a nonlinear diffusion PDE relevant to the lubrication flow of a thin layer of fluid—see Section 3.4.1 for the example code.

- `fun` is the name of the user function, `fun(t,u,x,y)`, that computes time derivatives (or time-steps) of quantities on the patches.
- `Xlim` array/vector giving the macro-space domain of the computation: patches are equi-spaced over the interior of the rectangle $[Xlim(1), Xlim(2)] \times [Xlim(3), Xlim(4)]$: if of length two, then use the same interval in both directions, otherwise `Xlim(1:4)` give the interval in each direction.
- `BCs` somehow will define the macroscale boundary conditions. Currently, `BCs` is ignored and the system is assumed macro-periodic in the domain.
- `nPatch` determines the number of equi-spaced spaced patches: if scalar, then use the same number of patches in both directions, otherwise `nPatch(1:2)` give the number in each direction.
- `ordCC` is the ‘order’ of interpolation across empty space of the macroscale mid-patch values to the edge of the patches for inter-patch coupling: currently must be in $\{0\}$.
- `ratio` (real) is the ratio of the half-width of a patch to the spacing of the patch mid-points: so `ratio` = $\frac{1}{2}$ means the patches abut; and `ratio` = 1 would be overlapping patches as in holistic discretisation: if

scalar, then use the same ratio in both directions, otherwise `ratio(1:2)` give the ratio in each direction.

- `nSubP` is the number of equi-spaced microscale lattice points in each patch: if scalar, then use the same number in both directions, otherwise `nSubP(1:2)` gives the number in each direction. Must be odd so that there is a central lattice point.
- `nEdge` is, for each patch, the number of edge values set by interpolation at the edge regions of each patch. May be omitted. The default is one (suitable for microscale lattices with only nearest neighbours interactions).

Output The *global* struct `patches` is created and set with the following components.

- `.fun` is the name of the user's function `fun(u,t,x,y)` that computes the time derivatives (or steps) on the patchy lattice.
- `.ordCC` is the specified order of inter-patch coupling.
- `.alt` is true for interpolation using only odd neighbouring patches as for staggered grids, and false for the usual case of all neighbour coupling—not yet implemented.
- `.Cwtsr` and `.Cwtsl` are the `ordCC`-vector of weights for the inter-patch interpolation onto the right and left edges (respectively) with patch:macroscale ratio as specified.
- `.x` is `nSubP(1) × nPatch(1)` array of the regular spatial locations x_{ij} of the microscale grid points in every patch.
- `.y` is `nSubP(2) × nPatch(2)` array of the regular spatial locations y_{ij} of the microscale grid points in every patch.
- `.nEdge` is, for each patch, the number of edge values set by interpolation at the edge regions of each patch.

3.4.1 If no arguments, then execute an example

```
100 if nargin==0
```

The code here shows one way to get started: a user's script may have the following three steps (arrows indicate function recursion).

1. configPatches2
2. ode15s integrator \leftrightarrow patchSmooth2 \leftrightarrow user's nonDiffPDE
3. process results

Establish global patch data struct to interface with a function coding a nonlinear 'diffusion' PDE: to be solved on 6×4 -periodic domain, with 9×7 patches, spectral interpolation couples the patches, each patch of half-size ratio 0.25, and with 5×5 points within each patch.

```
120 nSubP = 5;
121 configPatches2(@nonDiffPDE,[-3 3 -2 2], nan, [9 7], 0, 0.25, nSubP);
```

Set a Gaussian initial condition using auto-replication of the spatial grid.

```
128 x=reshape(patches.x,nSubP,1,[],1);
129 y=reshape(patches.y,1,nSubP,1,[],);
130 u0=exp(-x.^2-y.^2);
131 u0=u0.*(0.9+0.1*rand(size(u0)));
```

Initiate a plot of the simulation using only the microscale values interior to the patches: set x and y -edges to **nan** to leave the gaps. Start by showing the initial conditions of [Figure 6](#) while the simulation computes.

```
141 figure(1), clf
142 x=patches.x; y=patches.y;
143 x([1 end],:)=nan; y([1 end],:)=nan;
144 u = reshape(permute(u0,[1 3 2 4]), [numel(x) numel(y)]);
145 hsurf = surf(x(:),y(:),u');
146 axis([-3 3 -3 -0.001 1]), view(60,40)
147 title('Nonlinear diffusion PDE on patches: solving with initial condi
148 xlabel('space x'), ylabel('space y'), zlabel('u(x,y)')
149 drawnow
```

Figure 6: initial field $u(x, y, t)$ at time $t = 0$ of the patch scheme applied to a nonlinear ‘diffusion’ PDE: **Figure 7** plots the computed field at time $t = 3$.

Integrate in time using standard functions.

```
163 disp('Wait while we simulate h_t=(h^3)_xx+(h^3)_yy')
164 [ts,ucts]=ode15s(@patchSmooth2,[0 3],u0(:));
```

Animate the computed simulation to end with **Figure 7**.

```
171 for i=1:length(ts)
172     u = patchEdgeInt2(ucts(i,:));
173     u = reshape(permute(u,[1 3 2 4]), [numel(x) numel(y)]);
174     hsurf.ZData = u';
175     title(['Nonlinear diffusion PDE on patches: time = ' num2str(ts(i))]);
176     pause(0.1)
177 end
```

Upon finishing execution of the example, exit this function.

```
192 return
```

Figure 7: field $u(x, y, t)$ at time $t = 3$ of the patch scheme applied to a nonlinear ‘diffusion’ PDE with initial condition in [Figure 6](#).

```
193 end%if no arguments
```

Example of nonlinear diffusion PDE inside patches As a microscale discretisation of $u_t = \nabla^2(u^3)$, code $\dot{u}_{ijkl} = \frac{1}{\delta x^2}(u_{i+1,j,k,l}^3 - 2u_{i,j,k,l}^3 + u_{i-1,j,k,l}^3) + \frac{1}{\delta y^2}(u_{i,j+1,k,l}^3 - 2u_{i,j,k,l}^3 + u_{i,j-1,k,l}^3)$.

```
204 function ut=nonDiffPDE(t,u,x,y)
205     dx=diff(x(1:2)); dy=diff(y(1:2)); % micro-scale spacing
206     i=2:size(u,1)-1; j=2:size(u,2)-1; % interior points in patches
207     ut=nan(size(u)); % preallocate storage
208     ut(i,j,:,:) = diff(u(:,j,:,:),.^3,2,1)/dx^2 ...
209                   + diff(u(i,:,:),.^3,2,2)/dy^2;
210 end
```

3.4.2 The code to make patches

Initially duplicate parameters as needed.

```

224 if numel(Xlim)==2, Xlim=repmat(Xlim,1,2); end
225 if numel(nPatch)==1, nPatch=repmat(nPatch,1,2); end
226 if numel(ratio)==1, ratio=repmat(ratio,1,2); end
227 if numel(nSubP)==1, nSubP=repmat(nSubP,1,2); end

```

Set one edge-value to compute by interpolation if not specified by the user.
Store in the struct.

```

235 if nargin<8, nEdge=1; end
236 if nEdge>1, error('multi-edge-value interp not yet implemented'), end
237 if 2*nEdge+1>nSubP, error('too many edge values requested'), end
238 patches.nEdge=nEdge;

```

First, store the pointer to the time derivative function in the struct.

```

247 patches.fun=fun;

```

Second, store the order of interpolation that is to provide the values for the inter-patch coupling conditions. Spectral coupling is **ordCC** of 0 and -1 .

```

256 if ~ismember(ordCC,[0])
257     error('ordCC out of allowed range [0]')
258 end

```

For odd **ordCC** do interpolation based upon odd neighbouring patches as is useful for staggered grids.

```

265 patches.alt=mod(ordCC,2);
266 ordCC=ordCC+patches.alt;
267 patches.ordCC=ordCC;

```

Might as well precompute the weightings for the interpolation of field values for coupling. (Could sometime extend to coupling via derivative values.)

```

283 ratio=ratio(:)'; % force to be row vector
284 if patches.alt % eqn (7) in \cite{Cao2014a}

```

```

285 patches.Cwtsr=[1
286     ratio/2
287     (-1+ratio.^2)/8
288     (-1+ratio.^2).*ratio/48
289     (9-10*ratio.^2+ratio.^4)/384
290     (9-10*ratio.^2+ratio.^4).*ratio/3840
291     (-225+259*ratio.^2-35*ratio.^4+ratio.^6)/46080
292     (-225+259*ratio.^2-35*ratio.^4+ratio.^6).*ratio/645120 ];
293 else %
294     patches.Cwtsr=[ratio
295         ratio.^2/2
296         (-1+ratio.^2).*ratio/6
297         (-1+ratio.^2).*ratio.^2/24
298         (4-5*ratio.^2+ratio.^4).*ratio/120
299         (4-5*ratio.^2+ratio.^4).*ratio.^2/720
300         (-36+49*ratio.^2-14*ratio.^4+ratio.^6).*ratio/5040
301         (-36+49*ratio.^2-14*ratio.^4+ratio.^6).*ratio.^2/40320 ];
302 end
303 patches.Cwtsr=patches.Cwtsr(1:ordCC,:);
304 % should avoid this next implicit auto-replication
305 patches.Cwtsl=(-1).^((1:ordCC)'.-patches.alt).*patches.Cwtsr;

```

Third, set the centre of the patches in a the macroscale grid of patches assuming periodic macroscale domain.

```

314 X=linspace(Xlim(1),Xlim(2),nPatch(1)+1);
315 X=X(1:nPatch(1))+diff(X)/2;
316 DX=X(2)-X(1);
317 Y=linspace(Xlim(3),Xlim(4),nPatch(2)+1);
318 Y=Y(1:nPatch(2))+diff(Y)/2;
319 DY=Y(2)-Y(1);

```

Construct the microscale in each patch, assuming Dirichlet patch edges, and a half-patch length of `ratio(1) · DX` and `ratio(2) · DY`.

```

327 nSubP=nSubP(:)'; % force to be row vector
328 if mod(nSubP,2)==[0 0], error('configPatches2: nSubP must be odd'), e

```

```

329 i0=(nSubP(1)+1)/2;
330 dx=ratio(1)*DX/(i0-1);
331 patches.x=bsxfun(@plus,dx*(-i0+1:i0-1)',X); % micro-grid
332 i0=(nSubP(2)+1)/2;
333 dy=ratio(2)*DY/(i0-1);
334 patches.y=bsxfun(@plus,dy*(-i0+1:i0-1)',Y); % micro-grid
335 end% function

```

Fin.

3.5 *patchSmooth2(): interface to time integrators*

Subsubsection contents

Input	59
Output	60

To simulate in time with spatial patches we often need to interface a users time derivative function with time integration routines such as **ode15s** or **PIRK2**. This function provides an interface. It assumes that the sub-patch structure is *smooth* so that the patch centre-values are sensible macroscale variables, and patch edge values are determined by macroscale interpolation of the patch-centre values. Communicate patch-design variables to this function via the previously established global struct **patches**.

```

23 function dudt=patchSmooth2(t,u)
24 global patches

```

Input

- **u** is a vector of length **prod(nSubP) · prod(nPatch) · nVars** where there are **nVars** field values at each of the points in the **nSubP(1) × nSubP(2) × nPatch(1) × nPatch(2)** grid.
- **t** is the current time to be passed to the user's time derivative function.

- `patches` a struct set by `configPatches2()` with the following information used here.
 - `.fun` is the name of the user's function `fun(t,u,x,y)` that computes the time derivatives on the patchy lattice. The array `u` has size `nSubP(1) × nSubP(2) × nPatch(1) × nPatch(2) × nVars`. Time derivatives must be computed into the same sized array, but herein the patch edge values are overwritten by zeros.
 - `.x` is `nSubP(1) × nPatch(1)` array of the spatial locations x_{ij} of the microscale grid points in every patch. Currently it *must* be an equi-spaced lattice on both macro- and micro-scales.
 - `.y` is similarly `nSubP(2) × nPatch(2)` array of the spatial locations y_{ij} of the microscale grid points in every patch. Currently it *must* be an equi-spaced lattice on both macro- and micro-scales.

Output

- `dudt` is `prod(nSubP) · prod(nPatch) · nVars` vector of time derivatives, but with patch edge values set to zero.

Reshape the fields `u` as a 4/5D-array, and sets the edge values from macroscale interpolation of centre-patch values. [Section 3.6](#) describes `patchEdgeInt2()`.

```
76 u=patchEdgeInt2(u);
```

Ask the user function for the time derivatives computed in the array, overwrite its edge values with the dummy value of zero, then return to a to the user/integrator as column vector.

```
86 dudt=patches.fun(t,u,patches.x,patches.y);
87 dudt([1 end],:,:,:,:)=0;
88 dudt(:, [1 end],:,:,:)=0;
89 dudt=reshape(dudt,[],1);
```

Fin.

3.6 `patchEdgeInt2()`: sets 2D patch edge values from 2D macroscale interpolation

Subsubsection contents

Input	61
Output	62
Lagrange interpolation gives patch-edge values	63
Case of spectral interpolation	64

Couples 2D patches across 2D space by computing their edge values via macroscale interpolation. Assumes that the sub-patch structure is *smooth* so that the patch centre-values are sensible macroscale variables, and patch edge values are determined by macroscale interpolation of the patch-centre values. Communicate patch-design variables via the global struct `patches`.

20

function u=patchEdgeInt2(u)

21

global patches

Input

- `u` is a vector of length `nx · ny · Nx · Ny · nVars` where there are `nVars` field values at each of the points in the `nx × ny × Nx × Ny` grid on the `Nx × Ny` array of patches.
- `patches` a struct set by `configPatches2()` which includes the following information.
 - `.x` is `nx × Nx` array of the spatial locations x_{ij} of the microscale grid points in every patch. Currently it *must* be an equi-spaced lattice on both macro- and micro-scales.
 - `.y` is similarly `ny × Ny` array of the spatial locations y_{ij} of the microscale grid points in every patch. Currently it *must* be an equi-spaced lattice on both macro- and micro-scales.
 - `.ordCC` is order of interpolation, currently only `{0}`.

— `.Cwtsr` and `.Cwtsl`—not yet used

Output

- `u` is $\text{nx} \times \text{ny} \times \text{Nx} \times \text{Ny} \times \text{nVars}$ array of the fields with edge values set by interpolation.

Determine the sizes of things. Any error arising in the reshape indicates `u` has the wrong size.

```

66 [ny,Ny] = size(patches.y);
67 [nx,Nx] = size(patches.x);
68 nVars = round(numel(u)/numel(patches.x)/numel(patches.y));
69 if numel(u) ~= nx*ny*Nx*Ny*nVars
70     nSubP=[nx ny], nPatch=[Nx Ny], nVars=nVars, sizeu=size(u)
71 end
72 u = reshape(u,[nx ny Nx Ny nVars]);

```

With Dirichlet patches, the half-length of a patch is $h = dx(n_\mu - 1)/2$ (or -2 for specified flux), and the ratio needed for interpolation is then $r = h/\Delta X$. Compute lattice sizes from inside the patches as the edge values may be NaNs, etc.

```

82 dx = patches.x(3,1)-patches.x(2,1);
83 DX = patches.x(2,2)-patches.x(2,1);
84 rx = dx*(nx-1)/2/DX;
85 dy = patches.y(3,1)-patches.y(2,1);
86 DY = patches.y(2,2)-patches.y(2,1);
87 ry = dy*(ny-1)/2/DY;

```

For the moment assume the physical domain is macroscale periodic so that the coupling formulas are simplest. Should eventually cater for periodic, odd-mid-gap, even-mid-gap, even-mid-patch, dirichlet, neumann, ?? These index vectors point to patches and their two immediate neighbours.

```

98 %i=1:Nx; ip=mod(i,Nx)+1; im=mod(j-2,Nx)+1;
99 %j=1:Ny; jp=mod(j,Ny)+1; jm=mod(j-2,Ny)+1;

```

The centre of each patch (as `nx` and `ny` are odd) is at

```
106 i0 = round((nx+1)/2);
107 j0 = round((ny+1)/2);
```

Lagrange interpolation gives patch-edge values So compute centred differences of the mid-patch values for the macro-interpolation, of all fields. Assumes the domain is macro-periodic.

```
117 if patches.ordCC>0 % then non-spectral interpolation
118 error('non-spectral interpolation not yet implemented')
119 dmu=nan(patches.ordCC,nPatch,nVars);
120 % if patches.alt % use only odd numbered neighbours
121 % dmu(1,:,:)=(u(i0,jp,:)+u(i0,jm,:))/2; % \mu
122 % dmu(2,:,:) = u(i0,jp,:)-u(i0,jm,:); % \delta
123 % jp=jp(jp); jm=jm(jm); % increase shifts to \pm 2
124 % else % standard
125 dmu(1,:,:)=(u(i0,jp,:)-u(i0,jm,:))/2; % \mu\delta
126 dmu(2,:,:)=(u(i0,jp,:)-2*u(i0,j,:)+u(i0,jm,:)); % \delta^2
127 % end% if odd/even
```

Recursively take δ^2 of these to form higher order centred differences (could unroll a little to cater for two in parallel).

```
135 for k=3:patches.ordCC
136 dmu(k,:,:) = dmu(k-2,jp,:)-2*dmu(k-2,j,:)+dmu(k-2,jm,:);
137 end
```

Interpolate macro-values to be Dirichlet edge values for each patch ([Roberts & Kevrekidis 2007](#)), using weights computed in `configPatches2()` . Here interpolate to specified order.

```
145 u(nSubP,j,:)=u(i0,j,:)*(1-patches.alt) ...
146 +sum(bsxfun(@times,patches.Cwtsr,dmu));
147 u( 1,j,:)=u(i0,j,:)*(1-patches.alt) ...
148 +sum(bsxfun(@times,patches.Cwtsl,dmu));
```

Case of spectral interpolation Assumes the domain is macro-periodic. We interpolate in terms of the patch index j , say, not directly in space. As the macroscale fields are N -periodic in the patch index j , the macroscale Fourier transform writes the centre-patch values as $U_j = \sum_k C_k e^{ik2\pi j/N}$. Then the edge-patch values $U_{j\pm r} = \sum_k C_k e^{ik2\pi/N(j\pm r)} = \sum_k C'_k e^{ik2\pi j/N}$ where $C'_k = C_k e^{ikr2\pi/N}$. For N patches we resolve ‘wavenumbers’ $|k| < N/2$, so set row vector **ks** = $k2\pi/N$ for ‘wavenumbers’ $k = (0, 1, \dots, k_{\max}, -k_{\max}, \dots, -1)$ for odd N , and $k = (0, 1, \dots, k_{\max}, \pm(k_{\max} + 1) - k_{\max}, \dots, -1)$ for even N .

```
169 else% spectral interpolation
```

Deal with staggered grid by doubling the number of fields and halving the number of patches (**configPatches2** tests there are an even number of patches). Then the patch-ratio is effectively halved. The patch edges are near the middle of the gaps and swapped.

```
179 % if patches.alt % transform by doubling the number of fields
180 % error('staggered grid not yet implemented')
181 % v=nan(size(u)); % currently to restore the shape of u
182 % u=cat(3,u(:,1:2:nPatch,:),u(:,2:2:nPatch,:));
183 % altShift=reshape(0.5*[ones(nVars,1);-ones(nVars,1)],1,1,[]);
184 % iV=[nVars+1:2*nVars 1:nVars]; % scatter interp to alternate field
185 % r=r/2; % ratio effectively halved
186 % nPatch=nPatch/2; % halve the number of patches
187 % nVars=nVars*2; % double the number of fields
188 % else % the values for standard spectral
189 % altShift = 0;
190 % iV = 1:nVars;
191 % end
```

Now set wavenumbers in the two directions. In the case of even N these compute the +-case for the highest wavenumber zig-zag mode, $k = (0, 1, \dots, k_{\max}, +(k_{\max} + 1) - k_{\max}, \dots, -1)$.

```
200 kMax = floor((Nx-1)/2);
201 krx = rx*2*pi/Nx*(mod((0:Nx-1)+kMax,Nx)-kMax);
202 kMay = floor((Ny-1)/2);
```

```
203     kry = ry*2*pi/Ny*(mod((0:Ny-1)+kMay,Ny)-kMay);
```

Test for reality of the field values, and define a function accordingly.

```
210     if imag(u(i0,j0,:,:))==0, uclean = @(u) real(u);
211     else uclean = @(u) u; end
```

Compute the Fourier transform of the patch centre-values for all the fields. If there are an even number of points, then zero the zig-zag mode in the FT and add it in later as cosine.

```
220     Ck = fft2(squeeze(u(i0,j0,:,:,:)));
```

The inverse Fourier transform gives the edge values via a shift a fraction \mathbf{rx}/\mathbf{ry} to the next macroscale grid point. Initially preallocate storage for all the IFFTs that we need to cater for the zig-zag modes when there are an even number of patches in the directions.

```
231     nFTx = 2-mod(Nx,2);
232     nFTy = 2-mod(Ny,2);
233     unj = nan(1,ny,Nx,Ny,nVars,nFTx*nFTy);
234     u1j = nan(1,ny,Nx,Ny,nVars,nFTx*nFTy);
235     uin = nan(nx,1,Nx,Ny,nVars,nFTx*nFTy);
236     ui1 = nan(nx,1,Nx,Ny,nVars,nFTx*nFTy);
```

Loop over the required IFFTs.

```
242     iFT = 0;
243     for iFTx = 1:nFTx
244     for iFTy = 1:nFTy
245     iFT = iFT+1;
```

First interpolate onto x -limits of the patches. (It may be more efficient to product exponentials of vectors, instead of exponential of array—only for $N > 100$. Can this be vectorised further??)

```
254     for jj = 1:ny
255         ks = (jj-j0)*2/(ny-1)*kry; % fraction of kry along the edge
256         unj(1,jj,:,: ,iV,iFT) = ifft2( bsxfun(@times,Ck ...
257             ,exp(1i*bsxfun(@plus,altShift+krx',ks))));
```

```

258     u1j(1,jj,:::,iV,iFT) = ifft2( bsxfun(@times,Ck ...
259         ,exp(1i*bsxfun(@plus,altShift-krx',ks))));
260 end

```

Second interpolate onto y -limits of the patches.

```

266 for i = 1:nx
267     ks = (i-i0)*2/(nx-1)*krx; % fraction of krx along the edge
268     uin(i,1,:::,iV,iFT) = ifft2( bsxfun(@times,Ck ...
269         ,exp(1i*bsxfun(@plus,ks',altShift+kry))));
270     ui1(i,1,:::,iV,iFT) = ifft2( bsxfun(@times,Ck ...
271         ,exp(1i*bsxfun(@plus,ks',altShift-kry))));
272 end

```

When either direction have even number of patches then swap the zig-zag wavenumber to the conjugate.

```

279 if nFTy==2, kry(Ny/2+1) = -kry(Ny/2+1); end
280 end% iFTy-loop
281 if nFTx==2, krx(Nx/2+1) = -krx(Nx/2+1); end
282 end% iFTx-loop

```

Put edge-values into the u -array, using `mean()` to treat a zig-zag mode as cosine. Enforce reality when appropriate via `uclean()`.

```

290 u(end,:::,iV) = uclean( mean(unj,6) );
291 u( 1 ,:::,iV) = uclean( mean(u1j,6) );
292 u(:,end,:::,iV) = uclean( mean(uin,6) );
293 u(:, 1 ,:::,iV) = uclean( mean(ui1,6) );

```

Restore staggered grid when appropriate. Is there a better way to do this??

```

300 %if patches.alt
301 % nVars=nVars/2; nPatch=2*nPatch;
302 % v(:,1:2:nPatch,:)=u(:,1:nVars);
303 % v(:,2:2:nPatch,:)=u(:,nVars+1:2*nVars);
304 % u=v;
305 %end
306 end% if spectral

```

```
307 end% function patchEdgeInt2
```

Fin, returning the 4/5D array of field values with interpolated edges.

A Create, document and test algorithms

For developers to create and document the various functions, we use an idea due to Neil D. Lawrence of the University of Sheffield:

- Each class of toolbox functions is located in separate directories in the repository, say `Dir`.
- Create a LaTeX file `Dir/funs.tex`: establish as one LaTeX section that `\input{Dir/*.m}`s the files of the functions in the class, example scripts of use, and possibly test scripts, [Table 1](#).
- Each such `Dir/funs.tex` file is to be included from the main LaTeX file `Doc/devManual.tex` so that people can most easily work on one section at a time:
 - put `\include{funs}` into `Doc/devManual.tex`;
 - to include we have to use a soft link so at the command line in the directory `Doc` execute `ln -s ../Dir/funs.tex` ²
- Each toolbox function is documented as a separate subsection, with tests and examples as separate subsections.
- Each function-subsection and test-subsection is to be created as a MATLAB/Octave `Dir/*.m` file, say `Dir/fun1.m`, so that users simply invoke the function in MATLAB/Octave as usual by `fun1(...)`.

Some editors may need to be told that `fun1.m` is a LaTeX file. For example, TexShop on the Mac requires one to execute in a Terminal

```
defaults write TexShop OtherTeXExtensions -array-add "m"
```

- [Table 2](#) gives the template for the `Dir/*.m` function-subsections. The format for a example/test-subsection is similar.

²Such soft links are necessary for at least my Mac OSX and hopefully will work for other developers. Further, it has the advantage that auxiliary files are also located in the `Doc` directory.

Table 1: example `Dir/*.tex` file to typeset in the master document a function-subsection, say `fun.m`, and maybe the test/example-subsections.

```

1 % input *.m files for ... Author, date
2 %!TEX root = ../Doc/devManual.tex
3 \section{...}
4 \label{sec:...}
5 \localtableofcontents
6 introduction...
7 \input{../Dir/fun.m}
8 \input{../Dir/funExample.m}
9 ...
10 \begin{body}
11 \subsection{To do}
12 ...
13 \subsection{Miscellaneous tests}
14 \input{../Dir/funTest.m}
15 ...
16 \end{body}

```

- Any figures from examples should be generated and then saved for later inclusion with the following (which finally works properly for MATLAB 2017+)

```

set(gcf,'PaperPosition',[0 0 14 10])
print('-depsc2',filename)

```

Include with `\includegraphics[scale=0.85]{filename}`

Table 2: template for a function-subsection Dir/*.m file.

```

1 % Short explanation for users typing "help fun"
2 % Author, date
3 %!TEX root = ../Doc/devManual.tex

B Aspects of developing a ‘toolbox’ for patch dynamics

Section contents

B.1	Macroscale grid	71
B.2	Macroscale field variables	71
B.3	Boundary and coupling conditions	72
B.4	Mesotime communication	73
B.5	Projective integration	73
B.6	Lift to many internal modes	74
B.7	Macroscale closure	74
B.8	Exascale fault tolerance	75
B.9	Link to established packages	75

This appendix documents sketchy further thoughts on aspects of the development.

B.1 Macroscale grid

The patches are to be distributed on a macroscale grid: the j th patch ‘centred’ at position $\vec{X}_j \in \mathbb{X}$. In principle the patches could move, but let’s keep them fixed in the first version. The simplest macroscale grid will be rectangular (`meshgrid`), but we plan to allow a deformed grid to secondly cater for boundary fitting to quite general domain shapes \mathbb{X} . And plan to later allow for more general interconnect networks for more topologies in application.

B.2 Macroscale field variables

The researcher/practitioner has to know an appropriate set of macroscale field variables $\vec{U}(t) \in \mathbb{R}^{d\vec{u}}$ for each patch. For example, first they might be a simple average over a core of a patch of all of the micro-field variables; second, they might be a subset of the average micro-field variables; and third in

general the macro-variables might be a nonlinear function of the micro-field variables (such as temperature is the average speed squared). The core might be just one point, or a sizeable fraction of the patch.

The mapping from microscale variable to macroscale variables is often termed the restriction.

In practice, users may not choose an appropriate set of macro-variables, so will eventually need to code some diagnostic to indicate a failure of the assumed closure.

B.3 Boundary and coupling conditions

The physical domain boundary conditions are distinct from the conditions coupling the patches together. Start with physical boundary conditions of periodicity in the macroscale.

Second, assume the physical boundary conditions are that the macro-variables are known at macroscale grid points around the boundary. Then the issue is to adjust the interpolation to cater for the boundary presence and shape. The coupling conditions for the patches should cater for the range of Robin-like boundary conditions, from Dirichlet to Neumann. Two possibilities arise: direct imposition of the coupling action ([Roberts & Kevrekidis 2007](#)), or control by the action.

Third, assume that some of the patches have some edges coincident with the boundary of the macroscale domain \mathbb{X} , and it is on these edges that macroscale physical boundary conditions are applied. Then the interpolation from the core of these edge patches is the same as the second case of prescribed boundary macro-variables. An issue is that each boundary patch should be big enough to cater for any spatial boundary layers transitioning from the applied boundary condition to the interior slow evolution.

Alternatively, we might have the physical boundary condition constrain the interpolation between patches.

Often microscale simulations are easiest to write when ‘periodic’ in microscale

space. To cater for this we should also allow a control at perhaps the quartiles of a micro-periodic simulator.

B.4 Mesotime communication

Since communication limits large scale parallelism, a first step in reducing communication will be to implement only updating the coupling conditions when necessary. Error analysis indicates that updating on times longer the microscale times and shorter than the macroscale times can be effective ([Bunder et al. 2016](#)). Implementations can communicate one or more derivatives in time, as well as macroscale variables.

At this stage we can effectively parallelise over patches: first by simply using Matlab's `parfor`. Probably not using a GPU as we probably want to leave GPUs for the black box to utilise within each patch.

B.5 Projective integration

To take macroscale time steps, invoke several possible projective integration schemes: simple Euler projection, Heun-like method, etc ([Samaey et al. 2010](#)). Need to decide how long a microscale burst needs to be.

Should not need an implicit scheme as the fast dynamics are meant to be only in the micro variables, and the slow dynamics only in the macroscale variables. However, it could be that the macroscale variables have fast oscillations and it is only the amplitude of the oscillations that are slow. Perhaps need to detect and then fix or advise.

A further stage is to implement a projective integration scheme for stochastic macroscale variables: this is important because the averaging over a core of microscale roughness will almost invariably have at least some stochastic legacy effect. [Calderon \(2007\)](#) did some useful research on stochastic projective intergration.

B.6 Lift to many internal modes

In most problems the number of macroscale variables at any given position in space, $d_{\vec{U}}$, is less than the number of microscale variables at a position, $d_{\vec{u}}$; often much less (Kevrekidis & Samaey 2009, e.g.). In this case, every time we start a patch simulation we need to provide $d_{\vec{u}} - d_{\vec{U}}$ data at each position in the patch: this is lifting. The first methodology is to first guess, then run repeated short bursts with reinitialisation, until the simulation reaches a slow manifold. Then run the real simulation.

If the time taken to reach a local quasi-equilibrium is too long, then it is likely that the macroscale closure is bad and the macroscale variables need to be extended.

A second step is to cater for cases where the slow manifold is stochastic or is surrounded by fast waves: when it is hard to detect the slow manifold, or the slow manifold is not attractive.

B.7 Macroscale closure

In some circumstances a researcher/practitioner will not code the appropriately set of macroscale variables for a complete closure of the macroscale. For example, in thin film fluid dynamics at low Reynolds number the only macroscale variable is the fluid depth; however, at higher Reynolds number, circa ten, the inertia of the fluid becomes important and the macroscale variables must additionally include a measure of the mean lateral velocity/momentum (Roberts & Li 2006, e.g.).

At some stage we need to detect any flaw in the closure, and perhaps suggest additional appropriate macroscale variables, or at least their characteristics. Indeed, a poor closure and a stochastic slow manifold are really two faces of the same problem: the problem is that the chosen macroscale variables do not have a unique evolution in terms of themselves. A good resolution of the issue will account for both faces.

B.8 Exascale fault tolerance

Matlab is probably not an appropriate vehicle to deal with real exascale faults. However, we should cater by coding procedures for fault tolerance and testing them at least synthetically. Eventually provide hooks to a user routine to be invoked under various potential scenarios. The nature of fault tolerant algorithms will vary depending upon the scenario, even assuming that each patch burst is executed on one CPU (or closely coupled CPUs): if there are much more CPUs than patches, then maybe simply duplicate all patch simulations; if much less CPUs than patches, then an asynchronous scheduling of patch bursts should effectively cater for recomputation of failed bursts; if comparable CPUs to patches, then more subtle action is needed.

Once mesotime communication and projective integration is provided, a recomputation approach to intermittent hardware faults should be effective because we then have the tools to restart a burst from available macroscale data. Should also explore proceeding with a lower order interpolation that misses the faulty burst—because an isolated lower order interpolation probably will not affect the global order of error (it does not in approximating some boundary conditions ([Gustafsson 1975](#), [Svard & Nordstrom 2006](#)))

B.9 Link to established packages

Several molecular/particle/agent based codes are well developed and used by a wide community of researchers. Plan to develop hooks to use some such codes as the microscale simulators on patches. First, plan to connect to LAMMPS ([Plimpton et al. 2016](#)). Second, will evaluate performance, issues, and then consider what other established packages are most promising.
